# **RSNA Intracranial Hemorrhage Detection**

## **Competition Overview**

Intracranial hemorrhage, bleeding that occurs inside the cranium, is a serious health problem requiring rapid and often intensive medical treatment. For example, intracranial hemorrhages account for approximately 10% of strokes in the U.S., where stroke is the fifth-leading cause of death. Identifying the location and type of any hemorrhage present is a critical step in treating the patient.

Diagnosis requires an urgent procedure. When a patient shows acute neurological symptoms such as severe headache or loss of consciousness, highly trained specialists review medical images of the patient's cranium to look for the presence, location and type of hemorrhage. The process is complicated and often time consuming.

## What am i predicting?

In this competition our goal is to predict intracranial hemorrhage and its subtypes. Given an image the we need to predict probablity of each subtype. This indicates its a multilabel classification problem.

### **Competition Evaluation Metric**

Evaluation metric is weighted multi-label logarithmic loss. So for given image we need to predict probality for each subtype. There is also an any label, which indicates that a hemorrhage of ANY kind exists in the image. The any label is weighted more highly than specific hemorrhage subtypes.

**Note:** The weights for each subtype for calculating weighted multi-label logarithmic loss is **not** given as part of the competition. We will be using binary cross entropy loss as weights are not available

### **Dataset Description**

The dataset is divided into two parts

- Train
- 2. Test
- 1. Train Number of rows: 40,45,548 records. Number of columns: 2

Columns:

Id: An image Id. Each Id corresponds to a unique image, and will contain an underscore.

Example: ID\_28fbab7eb\_epidural. So the Id consists of two parts one is image file id ID\_28fbab7eb and the other is sub type name

**Label**: The target label whether that sub-type of hemorrhage (or any hemorrhage in the case of any) exists in the indicated image. 1 --> Exists and 0 --> Doesn't exist.

2. Test Number of rows: 4,71,270 records.

Columns:

**Id**: An image Id. Each Id corresponds to a unique image, and will contain an underscore.

Example: ID\_28fbab7eb\_epidural. So the Id consists of two parts one is image file id ID\_28fbab7eb and the other is sub type name

Competition evaluation metric is evaluated based on weighted log loss but we haven't given weights for each subtype but as per discussion from this thread <a href="https://www.kaggle.com/c/rsna-intracranial-hemorrhage-detection/discussion/109526#latest-630190">https://www.kaggle.com/c/rsna-intracranial-hemorrhage-detection/discussion/109526#latest-630190</a> any has a wieght of 2 than other types below sample is taken from the discussion threas

```
In [28]: from keras import backend as K
         def weighted_log_loss(y_true, y_pred):
             Can be used as the loss function in model.compile()
             -----
             class_weights = np.array([2., 1., 1., 1., 1., 1.])
             eps = K.epsilon()
             y_pred = K.clip(y_pred, eps, 1.0-eps)
                        y_true * K.log(      y_pred) * class_weights
             out = -(
                     + (1.0 - y_true) * K.log(1.0 - y_pred) * class_weights)
             return K.mean(out, axis=-1)
         def _normalized_weighted_average(arr, weights=None):
             A simple Keras implementation that mimics that of
             numpy.average(), specifically for this competition
             if weights is not None:
                 scl = K.sum(weights)
                weights = K.expand dims(weights, axis=1)
                 return K.sum(K.dot(arr, weights), axis=1) / scl
             return K.mean(arr, axis=1)
         def weighted_loss(y_true, y_pred):
             Will be used as the metric in model.compile()
             Similar to the custom loss function 'weighted_log_loss()' above
             but with normalized weights, which should be very similar
             to the official competition metric:
                 https://www.kaggle.com/kambarakun/lb-probe-weights-n-of-positives-scoring
             and hence:
                sklearn.metrics.log_loss with sample weights
             class_weights = K.variable([2., 1., 1., 1., 1.])
             eps = K.epsilon()
             y_pred = K.clip(y_pred, eps, 1.0-eps)
             loss = -(
                         y_true * K.log(
                                                 y_pred)
                    + (1.0 - y_true) * K.log(1.0 - y_pred))
             loss_samples = _normalized_weighted_average(loss, class_weights)
             return K.mean(loss_samples)
         def weighted_log_loss_metric(trues, preds):
             Will be used to calculate the log loss
             of the validation set in PredictionCheckpoint()
             class_weights = [2., 1., 1., 1., 1., 1.]
             epsilon = 1e-7
             preds = np.clip(preds, epsilon, 1-epsilon)
             loss = trues * np.log(preds) + (1 - trues) * np.log(1 - preds)
             loss_samples = np.average(loss, axis=1, weights=class_weights)
             return - loss_samples.mean()
In [29]: | filepath="model.h5"
         checkpoint = ModelCheckpoint(filepath, monitor='val loss', verbose=1, \
                                     save_best_only=True, mode='min')
         callbacks_list = [checkpoint]
```

For a single epoch we are going to train only last 5 layers of Efficient. Since we have a large number of images around 600k so its better to train the all the layers on the whole train dataset but due its high computation resources required to train we only goin to train last five layers on whole dataset and for rest of epochs we only train on a sample of dataset but will train all the layers.
